- Appendix 2 - Shoreline Oiling by Habitat

## **1.0 INTRODUCTION**

---

This document will describe the total extent of oiling, and the location of oil relative to different shoreline habitats of the Patuxent River and its tributaries. The degree of oiling at each location and habitat is categorized as light, moderate, or heavy. The procedures used to assess oiling distribution and evaluate data to arrive at these totals are presented below.

### **1.1 APPROACH TO DETERMINING THE LOCATION OF OIL IN THE PATUXENT RIVER SYSTEM**

Oiling in shoreline areas and interior areas were analyzed separately and by different methods. Assessment methods for the shoreline assessment relied on Shoreline Clean-up Assessment Teams (SCAT) data and the interior assessment relied on aerial photograph analysis. The two methodologies were used because: 1) the amount of oil in shoreline areas was much more dynamic than oil in interior areas; and 2) shorelines were being cleaned earlier in the response effort and natural processes reduced the amount of oil present along shorelines much more rapidly than for interior oiled areas; 3) it was difficult to assess the extent of shoreline oiling from aerial photographs because the bands of oil were often less than 1 meter wide and were sometimes located under tree or shrub canopies; and 4) interior oiling was difficult to assess from the ground because of the difficulty of moving through the marshes. For these reasons interior oiling was assessed by analyzing aerial photographs taken on April 24, 2000 and shoreline oiling was assessed from information gathered by SCAT on the ground.

## 2.0 SHORELINE ASSESSMENT

---

### 2.1 COLLECTION OF SCAT DATA

Field observations used to assess the degree of shoreline oiling were collected between April 13 and 24, 2000. Oiling pattern characteristics were assessed using the SCAT procedure. The SCAT procedure was developed during the *Exxon Valdez* oil spill, and has been refined over the past decade. The SCAT procedure is accepted as the benchmark for documenting shoreline-oiling characteristics using standardized terminology and procedures.

The goals of the SCAT program were to:

- Document the location, amount and character of oil on the shoreline;
- Provide the Planning and Operations Sections with accurate shoreline oiling information to aid in the decision-making process; and
- Formulate recommendations for appropriate clean-up methods, priorities and constraints.

Numerous individuals participated on the SCAT during the course of the response. Though an effort was made at maintaining consistency among team members, conflicting schedules among personnel did not always allow for full time participation. In addition, assignments were made to ensure that representative experience levels were spread among each team. SCAT participants included representatives from the following organizations:

- Maryland Department of Natural Resources (MDNR);
- Maryland Department of the Environment (MDE);
- National Oceanic and Atmospheric Association (NOAA);
- U.S. Fish and Wildlife Service (USFWS);
- U.S. Coast Guard (USCG);
- Pepco;
- ENTRIX, Inc. (representing Pepco);
- Polaris Applied Sciences (representing Pepco); and
- Gallagher Marine Systems, Inc. (representing Pepco).

The oiled and unoiled shoreline of affected portions of the Patuxent River and its tributaries were divided into shoreline segments. The segments were further subdivided based on the uniformity of shoreline sediments or substrate, and oiling conditions. Segments and subdivisions were assigned an alpha-numeric code. In some of the more heavily impacted segments, multiple surveys were conducted over the course of the clean-up. Subdivision boundaries between first, second and third surveys were not consistent.

### **2.1.1 Data Collected**

Oiling characteristics were entered on a standardized Shoreline Oiling Summary (SOS) form, accompanied with a map indicating segment and subdivision boundaries. Critical data fields on the SOS forms include width of the oiled area, distribution (or percent cover) by oil, and thickness of the deposited oil. A separate distribution was assigned to each oil thickness within the oiled area. It was fairly typical to have more than one distribution and thickness within the oiled area. Thus a given area (defined by a width and length specified on the SOS forms) might contain five percent cover by tarballs and 20% cover by a coating of oil. Shoreline types were indicated using the following ESI (Environmental Sensitivity Index) categories:

1. Seawalls, piers, and manmade structures;
2. Exposed, fine sand beaches;
3. Sheltered, fine sand beaches;
4. Coarse sand beaches;
5. Exposed tidal flats;
6. Rip rap;
7. Supratidal marshes, partially protected by elevation;
8. Freshwater marshes;
9. Sheltered tidal flats;
10. Fringing, intertidal marshes; and
11. Extensive intertidal marshes.

### **2.1.2 Data Gaps**

Following completion of the SCAT field surveys, it was noted that data gaps existed in several locations. To fill the gaps in shoreline coverage, aerial videotapes were reviewed. Based on this review, shoreline-oiling information was reconstructed and the data were entered into the database. Aerial videotapes were also used to determine worst case oiling conditions in segments where the amount of shoreline oiling was suspected of being greater prior to SCAT surveys.

## **2.2 ESTIMATE OF MAXIMUM OILING**

Estimation of maximum observed oiling categories for each location along the shoreline was completed in two steps. This was necessary because multiple surveys were conducted.

The first step was to calculate an overall-oiling category for each subdivision in each survey. When multiple distributions and thickness' were indicated on the forms for an individual subdivision, the following calculations were made:

- The oil distribution (percent cover) was evaluated as the sum total of oil distribution of each of the reported oil thickness';
- The overall oil thickness was a weighted average thickness calculated from a combination of each oil thickness observation weighted by its respective distribution using the following formula:

$$\sum_{i=1}^n Di * Ti / \sum_{i=1}^n Di$$

Where:

$n$  = Total number of thickness categories reported in the subdivision

$Di$  = Distribution reported for oil band i;

$Ti$  = Oil thickness reported for oil band i.

In the second step, the maximum oiling category was assessed for each portion of the shoreline. This was done by comparing oiling categories assessed for each survey. Due to continued mobility of the oil and on-going clean-up efforts, several of the more heavily impacted segments were surveyed on multiple occasions. Since the location of subdivision boundaries often changed from one survey to the next, new subdivisions often had to be created. The oiling category data used for each of these new subdivisions corresponded either: 1) to the survey where the oiling category was highest; or 2) when oiling categories were equal between surveys, to the situation where oil thickness was reported as highest. When oil thickness and oiling categories were equal for the same portion of the shoreline between two surveys, data from the later survey was generally used. At the end of this process, each section of shoreline was assigned the oil thickness, distribution, and width present when the maximum amount of oil was present.

A more detailed account of the SCAT process and results can be found in the final SCAT report titled "Summary of SCAT Activities and Data Management: Swanson Creek Incident" dated October 16, 2000. Data tables from the SCAT report are presented in Appendix A.

### 2.3 DEGREE OF OIL CLASSIFICATION

The Wetland Assessment Team used the data from the final SCAT report to categorize shorelines based on the amount of injury expected from the oil. These categories are different from those assigned by the SCAT. Light oiling was defined as oil with a thickness less than coat ( $> 0.01$  cm) or a distribution of less than 10% wherever it occurred in the spill zone. Areas with a thickness greater than coat and with a distribution greater than 10% were designated as either moderate or heavily oiled. Oiled areas in Swanson Creek that did not meet the criteria for light oiling received a heavy designation. The oil was initially trapped in Swanson Creek by booms so the fresher more toxic oil was concentrated there and these areas appeared to have more oil penetration beneath the surface layers of soil. Oiled areas outside Swanson Creek that did not meet the criteria for light oiling received a moderate oiling designation. The location of light,

moderate, and heavy shoreline parcels is shown in Swanson Creek Incident NRDA Oiling Classification Maps located in the map pockets at the end of this report.

### ***2.3.1 Calculation of Area Oiled***

The width and length of the oil band documented by SCAT for each subdivision were used to estimate the total area oiled. In some subdivisions, the width of oil is the estimated width at a time when oil thickness and distribution was greatest but when the width of the oiled area was not. The data collected for each subdivision was examined and the maximum width of oiling from any survey was used to calculate the area of oiling. This width is shown in “Max Width” column of Appendix 1B.

During various field visits, the Wetland Assessment Team noted oiling in five areas of shoreline that were not assessed by SCAT. These areas were assigned a light, moderate, or heavy oiling designation and an oiling width by the marsh group. The segments were then added to the maps and used in all calculations of oiled area. The group also realized that the widths assigned to the more heavily oiled shoreline segments did not account for remobilization of oil further back toward the interior of the marsh. The group agreed to incorporate a 5-meter-wide shoreline transitional area to account for the remobilized oil. The 5-meter-wide band is associated with all moderate and heavily oiled shoreline segments.

Data on each shoreline segment is contained in the spreadsheet in Appendix 1B, Oiled Widths and Areas of All Shoreline Segments. This data corresponds to the associated data set from the SCAT report presented in Appendix 1A. The complete data set is included as the electronic file NRDAoil.xls on the CD-ROM located in the pocket at the back of this report.

---

## 3.0 ANALYSIS OF INTERIOR OILING

---

### 3.1 COLLECTION OF DATA

Aerial photography was used to assign oiling categories to areas of interior marsh. Fixed wing, georectified aerial photos were taken by Nova Digital on April 24, 2000. These aerials were photomosaiced to produce composite photos of the major tributaries to the Patuxent River that may have contained areas of interior marsh.

#### *3.1.1 Heavy Interior Oiling*

Heavily oiled vegetation showed up as black patches on the photos. An analysis of the photos showed that heavy interior oiling only occurred in Swanson Creek.

#### *3.1.2 Interior Transitional Area*

During field visits, the Wetland Assessment Team realized that the edge of the interior oiled area was not visible on the photographs and agreed to add a 5-meter wide transition to the area visible in the photos. This area is called the transitional oiled areas on the NRDA Oiling Classification Maps included in the map pockets at the back of this report.

Some transitional areas were very irregular in shape and in some places totally surrounded unoiled marsh. These enclosed areas of unoiled marsh were generally small and were also assigned to the interior transitional category.

#### *3.1.3 Restricted Access Areas*

In some places, polygons of unoiled marsh had more than 80% of their perimeter oiled. Although no oil reached these areas, the oil may have restricted the movement of animals into the unoiled marsh and reduced services. The Wetland Assessment Team visually assessed the aerial photographs and these unoiled but affected areas were then assigned to a restricted access category (Table 4-1).

## **4.0 ASSESSMENT OF HABITAT TYPES AFFECTED BY OIL**

---

### **4.1 GENERAL HABITAT TYPES**

The eleven ESI shoreline types (see section 2.1.1) were classified into three general habitat types. ESI codes 1 and 6 were classified as manmade structures. ESI codes 2, 3, 4, 5, and 9 were classified as unvegetated areas. ESI codes 7, 8, 10, and 11 were classified as marshes. Many shoreline subdivisions were characterized with two or more ESI codes. It was assumed that when two or more ESI codes were assigned, the different habitats were arranged in bands one behind another. In order to calculate the area in each subdivision comprising the different general habitat types, the width of each subdivision was divided among the general habitat types using the following rules.

- If the segment was classified entirely as one general habitat type the entire width was assigned to that habitat type;
- If a subdivision contained both a manmade ESI code and an unvegetated or marsh ESI code no width was assigned to the manmade habitat type; and
- If a subdivision contained both unvegetated and marsh ESI codes the width was evenly divided between unvegetated habitat and marsh habitat.

The widths of each general habitat type were then used to calculate the area of each general habitat type in each subdivision. These widths are shown in the appropriate columns in Appendix 1B “Oiled Widths and Areas of All Shoreline Segments”. See Table 4-1 for a breakdown of oiled area by general habitat type.

**Table 4-1. Extent of Oiling by General Habitat Type (acres)**

Category	Manmade Shoreline	Beach Shoreline	Marsh Shoreline	Marsh Interior
Heavy	0.00	0.47	3.34	16.18
Moderate	0.65	6.40	12.01	
Light	0.85	3.24	7.87	
Transitional areas			32.60	7.87
Restricted Access Areas				4.11
Total acres	1.49	10.11	55.81	28.16
<b>Grand total:</b>		<b>95.58</b>		

Note: Sums in Table 4-1 (Total acres) are taken directly from the NRDAoil.xls spreadsheet which was used to calculate oiled area. Adding the reported values in Table 4-1 results in rounding errors.

### **4.2 SHORELINE MARSH HABITATS**

In order to associate oiling levels with specific marsh habitat types, each section of the shoreline containing marsh habitat was assessed for the plant community present. During the marsh

assessments conducted in July and September, members of the Wetland Assessment Team conducted a field reconnaissance of the entire shoreline to verify habitat types. Using McCormick<sup>1</sup> maps as a starting point, they recorded habitat boundaries for the shoreline areas. Since the McCormick maps were created in the 1970s, the field reconnaissance was conducted to verify the current accuracy. The field-corrected McCormick maps were then digitized as one layer of an ARCVIEW GIS database and overlain on a map of oiling characteristics. The two data sets were used to generate a table showing degree of oiling by habitat type (Appendix 2 and Table 4-2).

The McCormick maps often showed areas of species associations by designating both dominant and subdominant species and these were not changed during the field survey. These areas were assigned the habitat type of the dominant species. Any marsh areas for which habitat type was unknown were assigned a habitat type of *Spartina spp.* These areas will be apportioned to *Spartina alterniflora* and *Spartina cynosuroides* habitat.

#### **4.3 INTERIOR MARSH HABITATS**

Interior habitats were determined by comparing McCormick maps to aerial photographs with the aid of personal knowledge of the area. Members of the Wetland Assessment Team sketched habitat boundaries of *Typha*, *Spartina cynosuroides*, and *Phragmites australis* onto an aerial photograph taken in September 2000. Habitats were only determined for oiled areas. Areas east of the pipeline corridor were not assigned a habitat type. Area W1A is a mixture of areas dominated by *Typha*, *Spartina alterniflora*, *Spartina cynosuroides*, or *Scirpus sp.* This area was not broken down into separate habitat types because of the difficulty in delineating areas from the aerial photographs and because a single recovery curve has been proposed for the entire area. All other oiled interior areas appear to be predominantly *Spartina spp.* All the interior oiled areas designated as *Spartina cynosuroides* or *Spartina spp.* were assigned to the *Spartina spp.* habitat type. The absence on the McCormick maps of any *Spartina alterniflora* areas in Swanson Creek and the inclusion of *Spartina alterniflora* quads in the *Spartina cynosuroides* areas sketched by Wetland Assessment Team members makes this the most appropriate designation. These areas will be apportioned to *Spartina alterniflora* and *Spartina cynosuroides* habitat for the injury assessment. All habitat boundaries were digitized as a layer of an ARCVIEW GIS database and overlain on a map of oiling characteristics. The two data sets were used to generate a table of degree of oiling by habitat type (Table 4-2).

In areas where the SCAT shoreline subdivisions partially overlapped with delineated interior oiled areas the length of the SCAT subdivision was reduced to eliminate the overlap. In areas where the SCAT shoreline subdivisions totally overlapped with delineated interior oiled areas a width of 0 was used for the SCAT subdivision for calculations of areas. See the data notes in Appendix 1B “Oiled Widths and Areas of All Shoreline Segments” for details on which subdivisions were affected.

## Addendum

---

The Extent of Oiling Report and the Wetland Injury Report differ in the number of acres that were reported as oiled. This difference is not an error but results from differences in the treatment of heavily oiled interior marsh and interior transitional areas in the two reports. The area of heavily oiled marsh was determined from aerial photographs taken of the spill site. During the damage assessment, the marsh assessment group agreed that a 5-meter wide band adjacent to the heavily oiled marsh would be added to account for areas that were oiled but were not visible on the aerial photographs. This 5 meter wide band was designated as the interior transitional area in Table 4-2 of the Extent of Oiling Report and treated as a separate oiling category.

In the estimating the wetland injury, the marsh assessment group agreed that the interior transitional areas suffered half the injury of the heavily oiled interior marsh. To facilitate the calculation of injury in the Wetland Injury Report, the acreage of the interior transition area associated with each species was divided by two and added to the area of heavy interior oiling. For any heavily oiled interior injury category, the acreage from the Wetland Injury Report can be calculated by adding one half the acreage from the interior transition area to the acreage from the injury category in Extent of Oiling Report. For example, Exhibit 7 of the Wetland Injury Report shows 2.3 acres of heavily oiled interior *Typha angustifolia* which includes 1.49 acres of heavily oiled marsh that was visible on the aerial photographs plus one half of the 1.63 acres of *T. angustifolia* from the adjacent interior transitional area. The 1.49 acres of heavily oiled interior *T. angustifolia* marsh and the 1.63 acres if interior transitional *T. angustifolia* marsh are reported separately in Table 4.2 of the Extent of Oiling Report. The same method of calculation can be used to reconcile the acreage of *Spartina* injury, W1A injury, and the total acres impacted in the two reports.

**Table 4-2. Extent of Marsh Oiling by Species (acres)**

	<i>Spartina alterniflora</i>	<i>Spartina cynosuroides</i>	<i>Typha angustifolia</i>	<i>Iva frutescens</i>	<i>Spartina spp.</i>	Other	W1A	Total
Light Shoreline	3.04	1.07	0.13	0.13	3.30	0.19		7.86
Moderate Shoreline	6.99	0.87	0.02	0.22	1.42	2.49		12.01
Heavy Shoreline	1.25	1.39	0.16		0.54			3.34
Shoreline Transitional Area								32.60
Heavy Interior Oiling			1.49		9.02		5.68	16.18
Interior Transitional Area			1.63		4.75		1.49	7.87
Restricted Access Area			1.03		2.64		0.44	4.11
<b>Grand Total:</b>								<b>83.99</b>

Notes:

"*Spartina spp.*". in shoreline areas are areas that were shown as marsh on the SCAT data and were not shown on the digitized habitat maps

"Other" category includes *Phragmites*, *S. patens* and areas that show up as marsh on the SCAT data but another shoreline type on the digitized habitat map

See Appendix 2 for more details from the digitized habitat maps

*Notes:*

*NRDAoil is a combination of Appendix 1A and Appendix 1B*

*NRDAoil is the same as the spreadsheet found in "Summary of SCAT Activities and Data Management: Swanson Creek Incident" with the following exceptions  
Columns L through R are added.*

*NRDA 10% category is an assigned oiling category based on the SCAT data.  
If the distribution is greater than 10% and the thickness of oil is greater than .01 then  
a category of heavy was assigned for locations inside Swanson Creek and a category  
of moderate was assigned everywhere else.*

*All other areas with oiling were assigned to the light category*

*Maximum oiling widths are added.*

*The maximum width is the maximum width of the oiled band reported at any survey for that segment.*

*The segments where the width was changed are highlighted in blue.*

*The maximum widths are used to calculate acreage.*

*The width of each shoreline type is the maximum width except where multiple habitat types are present.*

*Where more than one habitat type is present no width is assigned to the manmade category.*

*Where both beach and marsh habitat types are present, half the width is assigned to each category.*

*ESI codes 1&6 = manmade; 2-5 and 9 = beaches; 7&8, 10&11 = marsh*

*6 new sections have been added as rows to the spreadsheet*

*NRD5-PC, NRD4-IC, NRD3-CC and NRD6-THC were areas upstream of SCAT  
coverage where oiling was observed. These areas were assigned a light oiling  
category and a 1 meter width.*

*NRD2-SC and NRD1-SC are islands in Swanson Creek with no SCAT info. They were  
assigned a heavy oiling category and a width equal to section W1X (3meters)*

*WIY, WIZ, WIAA, W1BB, W1GG, W1DD (colored yellow) have widths changed to 0  
because they are part of the interior oiling maps.*

*WIDD has width changed to 5 meters because there is partial overlap with interior  
oiling. The width was changed to the width of adjacent parcel W1CC and the length  
was reduced by the amount of overlap. The width was originally 200 meters.*

*W1CC, W1DD, W1FF and W2V had lengths (red cells) reduced by the amount of  
overlap with interior oiling polygons*

*E-2e\_1 and E-2d\_1 have width changed to 0 (colored yellow) because they were  
retained by mistake in the SCAT spreadsheets. The segment was replaced by segments  
from video surveys which showed heavier oiling.*

*A 5 meter Transition area has been added to areas of moderate and heavy oiling adjacent to oiled shoreline marks  
These Shoreline Transition Areas will be considered light oiling.*

*"Sorted" sheet is MaxoilCat sorted by NRDA Oiling Category with acreages calculated in Cells W1 - W19.*

The logo for Environmental Science Services, Inc. (ESS) is located at the top left of the page. It features a stylized green globe graphic on the left, followed by the letters "ES" in a large, bold, green font. A smaller "2" is positioned above the "S". To the right of the graphic, the company name "Environmental Science Services, Inc." is written in a black, sans-serif font, with a horizontal line underneath the "Environmental Science Services" part.
